㉔ TRANSVERSE DISCHARGE PUMPING TYPE PULSE LASER OSCILLATING DEVICE.

㉕ This invention relates to a transverse discharge pumping type pulse laser oscillating device including an electron capturing gas, especially to the configuration of preliminary ionization electrodes (4a, 4b, 8a, 8b). A transverse discharge exciting type pulse laser oscillating device according to this invention has preliminary ionization parts such that the dominant parts of corona discharge are directed to the part between main electrodes (1, 2) and the developing lengths (1) of the corona discharge are long. The long developing lengths (1) increase the quantity of emitted ultraviolet rays and the electrodes (4a, 4b, 8a, 8b) are so arranged that the air between the main electrodes (1, 2) is irradiated with ultraviolet rays emitted from near the initiating regions of the corona discharge the initiating regions emitting light whose intensity is greater than those of other regions in the corona discharges. Thereby a homogeneous main discharge is obtained and the efficiency of the

laser oscillation is improved.

F1 G.1

EP 0 532 751 A1

TECHNICAL FIELD

The present invention relates to a transverse discharging excitation pulse laser oscillator apparatus including electron affinity gas, in particular relates to the constitution of its pre-ionization electrodes.

BACKGROUND ART

FIG.5 is a cross-sectional drawing showing a discharging electrode of a conventional transverse discharge excitation pulse laser oscillator apparatus shown for example, in DOE/SF/90024-T2 (1977) wherein: (1) is a first main electrode; (1a) is a 1/4 inch outer diameter tube which constitutes a tip electrode; (2) is a second main electrode (sic) which is produced between main electrodes (1) and (2); (4) is an auxiliary electrode comprised of a wire disposed in the vicinity of the first main electrode (1); (5) is a dielectric material pipe comprised of quartz pipe of approximately 5 mm outer diameter which is disposed in a manner that it contains the auxiliary electrode (4) inside and touches with the first main electrode (1); (6a) and (6b) are corona discharges taking place on the surface of the dielectric material pipe; and (7a) and (7b) are corona discharge starting points.

Next, explanation is given on its action. First, upon applying a voltage across the first main electrode (1) and the auxiliary electrode (4), corona discharges (6a) and (6b) start from a points (7a) and (7b) at which dielectric material (5) and the first main electrode (1) touch to each other in a manner that they cover the dielectric material pipe (5). Ultra-violet radiation is radiated from these corona discharges (6a) and (6b), thereby laser gas existing between the main electrodes (1) and (2) is pre-ionized. Subsequently, when a voltage is applied across the main electrodes (1) and (2), pre-ionized gas starts to discharge and then the main discharge (3) takes place. The laser gas is excited by this main discharge (3), thereby the laser starts to oscillate in a direction which is perpendicular with respect to the plane of sheet. Since the conventional transverse discharge excitation pulse laser oscillator apparatus is constituted as has been described above, there has been a problem that the ultra-violet radiation taking place in the vicinity of the corona discharge starting points (7a) and (7b), at which light emission caused by the corona discharge was strong, was not radiated efficiently into the space between the main discharge electrodes (1) and (2).

The present invention has been done in consideration of the problem as has been described above, light-emission amount of the ultra-violet ra-

diation can be made strong and, in addition to that, by taking a configuration through which this ultra-violet radiation can be illuminated efficiently into the space between the main electrodes, even in the case that a strong electron affinity gas such as F₂ gas is included in the laser gas, a uniform discharge can be realized, thus as a result, it purposes to obtain a transverse discharge excitation pulse laser oscillator apparatus which can oscillate with a high efficiency.

DISCLOSURE OF INVENTION

In a transverse discharge excitation pulse laser oscillator apparatus in accordance with the present invention, by making the extension length of the corona discharge long, a pre-ionized discharge is constituted in a manner that a strong part of the corona discharge is directed toward the space between the main electrodes. Owing to such the constitution, also by making the extension length of the corona discharge long, the light-emission amount of the ultra-violet radiation is enhanced, and the electrodes are disposed in a manner that the ultra-violet radiation taking place in the vicinity of the corona discharge starting point at which the light-emission amount is strong among the corona discharges can illuminate the air in the space between the main electrodes.

BRIEF DESCRIPTION OF DRAWINGS

FIG.1 is a side cross-sectional view showing a transverse discharge excitation pulse laser oscillator apparatus in accordance with one embodiment of the present invention, FIG.2 is a side cross-sectional view of a corona discharge part for explaining a corona discharge extension length of the present invention, FIG.3 and FIG.4 are side cross-sectional views of transverse discharge excitation pulse laser oscillator apparatus showing other embodiments of the present invention. FIG.5 is a side cross-sectional view of a transverse discharge excitation pulse laser oscillator apparatus of prior art.

BEST MODE FOR CARRYING OUT THE INVENTION

In the following, explanation is given on one embodiment of the present invention referring to drawings. FIG.1 is a cross-sectional view in a plane perpendicular with respect to the laser oscillation optical axis of the a transverse discharge excitation pulse laser oscillator apparatus, and in the drawing, (4a) and (4b) are auxiliary electrodes of cylindrical shape which are disposed with a distance on both sides of a second main electrode (2), (5a) and (5b) are dielectric material pipes having almost the

same inner diameter as an outer diameter of the auxiliary electrodes (4a) and (4b), and in this case, they are made of alumina ceramics composed of alumina as its main composition. (8a) and (8b) are corona starting electrodes which are wire-shaped conductors disposed at parts near the main electrodes (1) and (2) among the outer peripheries of the dielectric material pipes (5a) and (5b) in a manner that they are kept at the same potential as that of the second main electrode (2), then (6a), (6b), (6c), and (6d) are corona discharges, (7a), (7b), (7c), and (7d) are corona discharge starting points at which the corona discharges (6a), (6b), (6c), and (6d) starts, (9) is a center point of the electrode surface of the first main electrode (1) which is facing to the second main electrode (2), (10) is a first direction determined by a straight line connecting between the corona starting point (7c) and the center point (9), (11) is a straight line obtained by an intersection of a plane which is perpendicular with respect to an extending direction of the corona discharge (6a) on the periphery of the corona starting electrode (8b) and a plane which is perpendicular with respect to a laser oscillation optical axis, and it indicates a second direction.

Upon applying a voltage across the second main electrode (2) and the auxiliary electrodes (4a) and (4b), an electrical field concentration takes place in the vicinity of the corona starting electrodes (8a) and (8b) which are connected in a manner that they keep the same potential as that of the second main electrode (2), then corona discharge starts first at those parts of (7a), (7b), (7c), and (7d) at which the corona starting electrodes (8a) and (8b) are close to the dielectric material pipes (5a) and (5b). The constitution of this drawing corresponds to a case of the surface-propagating corona discharge in the case of the presence of electrodes in the back surface, the corona discharges starting from the corona discharge starting points (7a), (7b), (7c), and (7d) develops along the surface of the dielectric material pipes (5a) and (5b) to form corona discharges (6a), (6b), (6c), and (6d). The extension length of the corona discharge (6a) is indicated by a notation 1. The extension length 1 of the corona discharge equals approximately to a half of the outer circumferential length of the dielectric material pipe (5) in this case.

In FIG.2, various shapes of the corona discharges as well as the corona discharge extension lengths thereof are shown. FIG.2(a) shows a case that two corona starting electrodes (8a) and (8b) are disposed on the surface of the dielectric material pipe (5) composed of cylindrical pipe, FIG.2-(b) shows a case that four corona starting electrodes (8a), (8b), (8c), and (8d) are disposed on the surface of the dielectric material pipe (5) composed

5 of cylindrical pipe, FIG.2(c) shows a case that one corona starting electrode (8) is disposed on the surface of the dielectric material pipe (5) composed of square-shaped pipe, and FIG.2(d) shows a case that a corona starting electrode (8) is wound spirally on the surface of the dielectric material pipe (5) composed of cylindrical pipe. In FIG.1 and FIG.2(a), (b), and (c), the corona starting electrodes are electrodes extending in the direction perpendicular with respect to the plane of sheet. As in the case of FIG.1 and FIG.2(c), in case that only one corona starting electrode (8) is present on the periphery of the dielectric material pipe (5), and in addition to that, it is extended in the direction of laser optical axis, the extension length 1 of the corona discharge equals approximately to a half of the circumferential length of the dielectric material pipe (5) when it is seen on a cross-section perpendicular to the laser optical axis. On the other hand, as in FIG.2(a), (b), and (d) in case that corona starting electrodes (8) are disposed with a constant pitch on the periphery of the dielectric material pipe (5), the extension length 1 of the corona discharge equals approximately to a half of this pitch. As the result that the light-emission amount from the corona discharge was measured on various shaped electrodes, it has been found that, as far as the outer shape of the dielectric material pipe (5) was the same, configurations of FIG.1 and FIG.2(c) could give the greatest amount of light emission. For example, in the case of FIG.2(a) in which the corona discharge extension length becomes half comparing with FIG.1, the light-emission amount of ultra-violet radiation also becomes half. And, in the case of FIG.2(b) in which the corona discharge extension length becomes 1/4 comparing with FIG.1, the light-emission amount of ultra-violet radiation diminishes to 1/4. That is, it was found that, in spite of covering almost all over the surface of the dielectric material pipe (5) with the corona discharge (6), an electrode configuration having a longer corona discharge extension length could give more emission amount of ultra-violet radiation, and in addition to that, the emission amount of ultra-violet radiation was proportional to the extension length 1 of the corona discharge. And, precise measurements of the emission amount of the ultra-violet radiation from the corona discharge (6) revealed that the emission amount was great in the vicinity of corona discharge starting points (7) and it diminished as proceeding up to the tip of the corona discharge (6).

55 From the result described above, it was revealed that by making the extension length 1 of the corona discharge longer and disposing the corona discharge starting points (7) in a manner that they faced to the place at which the main discharge (3)

took place, the amount of the pre-ionization could be increased. And, since, due to the corona discharge (6), the ultra-violet radiation propagates in the gas space while it is diverging, moreover it is absorbed by gas on its way of propagation, a closer disposition of the occurrence points of the corona discharges (6) to the main electrodes (1) and (2) can make the amount of the pre-ionization more. However, since an excessive proximity of the dielectric material pipes (5) to the first main electrode (1) eventually introduces a discharge between the first main electrode (1) and the corona starting electrodes (8), it is necessary to separate them with keeping a more distance than a certain extent. Since the first main electrode (1) is disposed at a more distant point from the corona discharge (6) than the second main electrode (2) is, it is desirable to select a position at which the ultra-violet radiation is efficiently illuminated on the main electrode (1). That is, in FIG.1, since the ultra-violet radiations of strong intensity emitted in the vicinity of the corona discharge starting points (7) is strongly radiated in a second direction (11), at a time when this second direction (11) coincides with the first direction (10) connecting the center point (9) of the first main electrode (1) and the corona discharge starting points (7c), the amount of the pre-ionization becomes largest. Denoting the angle between the first direction (10) and the second direction (11) to be θ , the amount of the pre-ionization becomes proportional to $\cos\theta$.

Actual experiments using an excimer laser including fluorine gas at gap lengths $g = 10 - 30$ mm showed that;

laser oscillations with a comparatively high efficiency could be obtained, if,

(1) when $\theta = 0 - 72.5$ degrees,

I is such that, $I = 1 \times \cos\theta = 3$ mm or more,

(2) and when $\theta =$ more than 72.5 degrees (in case that the corona discharge starting point (7) is hidden back side),

I is such that, $I = 1 \times 0.3 = 3$ mm or more.

In the above equations, parameter I is a quantity expressing the strength of the pre-ionization. If $I = 5$ mm or more, the laser oscillation efficiency increases further (3 % or more). In a case that the corona discharge (6) is carried out at only one side of the main discharge (2) as is shown in FIG.1, it is necessary to take a value of the parameter I to be twice as the abovementioned value.

And, it is found that, when the minimum separation distance L (14) between the first main electrode (1) and the dielectric material pipes (5) is taken to be 1.05 times or more and 1.5 times or less of the minimum gap length g between the first main electrode (1) and the second main electrode (2), the laser oscillates in a good efficiency, and moreover, and no arc discharge takes place be-

tween the first main electrode (1) and the dielectric material pipes (5). In FIG.1, the minimum separation distance L (14) between the first main electrode (1) and the dielectric material pipes (5) is taken to be 1.17 times of the minimum gap length g .

FIG.3 is a side cross-sectional view showing other embodiment of the present invention. The dielectric material pipes (5) are disposed in such a manner as they are buried in on both sides of the center part of the second main electrode (2). And, the corona starting electrodes (8) take a unitary construction with the second main electrode (2). By taking this construction, the corona starting electrodes (8) can be omitted and thereby not only the configuration becomes simple, but also, in case that a gas flow (12) is let being flowing between the main electrodes (1) and (2), it becomes possible to let the gas flow in a high speed owing to that there is no obstacle impeding against the gas flow. Therefore, it is convenient to operate the laser in a high repetition rate mode.

FIG.4 is a side cross-sectional view showing another embodiment of the present invention. The dielectric material pipes (5a) and (5b) are disposed in such a manner as they are buried in the second main electrode (2) and at the same time the dielectric material pipes (5a) and (5b) are disposed with letting them floating from the second main electrode (2) so that they can keep a distance d or more except that they come close thereto or they make contact with the second main electrode (2) at its parts (13a) and (13b). If the distance d is made thicker than the thickness of the dielectric material pipe (5), the corona discharge (6) is extended on its extension length as is shown in FIG.4, thereby the pre-ionization amount can be increased. And, since the dielectric material pipes (5) are disposed in such a manner as they are buried in the second main electrode, they cannot be an obstacle against the gas flow (12) and hence the gas can be circulated with a high speed, hence a high repetition rate operation of the laser becomes possible.

And, although, in FIG.1, FIG.2 (a), (b), and (c), the corona starting electrodes (8) were taken to be a uniform shape in the laser optical axis direction, a non-uniform shape such as, for example, having projections sporadically along the laser optical axis can also exhibit the same effect.

Also, although explanation has been given on a case using an alumina ceramics containing alumina as its main composition as for the dielectric material on an excimer laser case, certain other materials can also exhibit the same effect for different laser cases.

INDUSTRIAL APPLICABILITY

As has been described above, according to the present invention, owing to the lengthening of the extension length of the corona discharge and the pre-ionization by the illumination of ultra-violet radiation emitted from a strong part of the corona discharge on the laser gas between the main electrodes, a uniform main discharge can be obtained and thereby the laser oscillation efficiency becomes high.

Claims

1. In a transverse discharge excitation pulse laser oscillator apparatus which is provided with a first and a second main electrodes which are disposed in a manner that they are facing to each other over a specified length in the laser optical axis direction, dielectric material hollow cylindrical pipes (or pipe) disposed on both sides (or one side) of said second main electrode with keeping a distance, auxiliary electrodes (or electrode) disposed inside said dielectric material pipes (or pipe), corona starting electrodes which are provided in the vicinity of or with keeping contact with said dielectric material pipes (or pipe) and whose potential is kept at the same as that of said second main electrodes (or electrode), and in which corona discharges start from said corona starting electrodes and they are developed and extended over the surface of said dielectric material pipes (or pipe) by applying a voltage across said second main electrode and said corona starting electrodes as well as said auxiliary electrodes (or electrode), thereby the laser gas existing between said first and second main electrodes is pre-ionized by the ultra-violet radiation generated from the said corona discharges, thus a uniform main discharge is produced in a space between said first and second electrodes and the laser gas is excited thereby, in case that the corona starting electrodes are provided in the vicinity of the dielectric pipes (or pipe) with keeping a pitch, a length of a half of this pitch is denoted by a notation 1, and in cases other than the above case, a length of a half of outer circumferential length of the dielectric material pipes (or pipe) on a cross-section perpendicular with the laser optical axis is denoted also by a notation 1, and in the cross-section perpendicular with respect to the laser optical axis, defining a first direction by a straight line connecting a center point on the side facing to the second main electrode among the surface of the first main electrode and the corona discharge starting

5 point at which the corona starting electrode starts the corona discharge in the vicinity of the dielectric material pipe, and then defining a second direction by a straight line produced by making a plane perpendicular with respect to the direction the corona discharge develops due to the proximity of the corona starting electrode cross with a plane perpendicular with respect to the laser oscillation optical axis, then denoting an angle produced between said first and second directions by a notation θ , and when

$$10 \theta = 0 - 72.5 \text{ degrees,}$$

15 defining the measure of the strength of the pre-ionization as $I = 1 \times \cos\theta$, whereas when

$$20 \theta = 72.5 \text{ degrees or more,}$$

25 defining the measure of the strength of the pre-ionization as $I = 1 \times 0.3$, a transverse discharge excitation pulse laser oscillator apparatus characterized in that, in the case that the dielectric material is disposed on both sides of the second main electrode, $I = 3 \text{ mm or more}$, whereas in the case that the dielectric material is disposed on one side of the second main electrode, $I = 6 \text{ mm or more}$.

- 30 2. A transverse discharge excitation pulse laser oscillator apparatus stated in claim 1 and characterized in that, in the case that the dielectric material is disposed on both sides of the second main electrode, the measure of the strength of the pre-ionization I is, $I = 5 \text{ mm or more}$, whereas in the case that the dielectric material is disposed on both sides (sic) of the second main electrode, $I = 10 \text{ mm or more}$.
- 35 3. A transverse discharge excitation pulse laser oscillator apparatus stated in claim 1 and claim 2 and characterized in that, denoting the minimum gap length between the first main electrode and the second main electrode by a notation g , the minimum separation distance between the first main electrode and the dielectric material is taken to be 1.05 times or more and 1.5 times or less of said minimum gap length g .
- 40 4. A transverse discharge excitation pulse laser oscillator apparatus stated from claim 1 to claim 3 and characterized in that said dielectric material pipes are disposed in such a manner as they are buried in the second main electrode and at the same time the dielectric pipes are disposed in a manner that they keep a

certain distance d from the second main electrode with the exception of proximity or contact with the second main electrode or with the corona starting electrodes at some parts, and in addition to that, the distance d is more than the thickness of the dielectric material pipe.

5

5. A transverse discharge excitation pulse laser oscillator apparatus stated from claim 1 to claim 4 and characterized in that said dielectric material pipes are made of alumina ceramics composed of alumina as its main composition, and said laser is an excimer laser.
